# SAGE MICROSYSTEMS EAST

Selling & Supporting the Best in 8-Bit Software

(New Lower Prices on Many Items!)

- Automatic, Dynamic, Universal Z-Systems: Z3PLUS for CP/M-Plus computers, NZCOM for CP/M-2.2 computers (now only \$49 each)
- XBIOS: the banked-BIOS Z-System for SB 180 computers (\$50)
- PCED — the closest thing to Z-System ARUNZ, and LSH under MS-DOS (\$50)
- DSD: Dynamic Screen Debugger, the fabulous full-screen debugger and simulator (\$50)
- ZSUS: Z-System Software Update Service, public-domain software distribution service (write for a flyer with full information)

- "Perfect Systems"

- Backgrounder ii: CP/M-2.2 multitasker (now only \$49)

- ZSDOS/ZDDOS: date-stamping DOS (\$75, \$60 for ZRDOS owners, \$10 for Programmer's Manual)

- DosDisk: MS-DOS disk-format emulator, supports subdirectories and date stamps (\$30 standard, \$35 XBIOS BSX, \$45 kit)

- JetFind: super fast, extremely flexible regular-expression text file scanner (now only \$25)

- \* ZMATE: macro text editor and customizable wordprocessor (\$50)

- BDS C — complete pkg including special Z-System version (now only \$60)

- Turbo Pascal — with new loose-leaf manual (\$60)

- s-ZMAC — Al Hawley's Z-System macro assembler with linker and librarian (\$50 with documentation on disk, \$70 with printed manual)

- SLR Systems (The Ultimate Assembly Language Tools)

- Z80 assemblers using Zilog (Z80ASM), Hitachi (SLR180), or Intel (SLRMAC) mnemonics, and general-purpose linker SLRNK

- TPA-based (\$50 each tool) or virtual-memory (\$160 ea ch tool)

neNightOwl (advanced telecommunications, CP/M and MS-DOS versions)

- MEX-Plus: automated modem operation with scripts (\$60)

- MEX-Paek: remote operation, terminal emulation (\$100)

Next-day shipping of most products with modem download and support available. Order by phone, mail, or modem. Shipping and handling: \$3 USA, \$4 Canada per order; based on actual cost elsewhere. Check, VISA, or MasterCard. Specify exact disk formats acceptable.

# EDITOR'S COMMENTS

---

## Here it is, the new and improved

version of TCJ. It has taken considerably longer than I thought, but then doesn't anything with computers these days. Before I talk about the articles, a few comments on the new format.

I have included a small box at the top of each article to help readers understand what the article is about. It has three lines and typically the first will be the main idea. Our next ten years article is the feature article and as such the header states that fact.

Next item in the box is the level of computer skills needed or in the case of the feature article, it is for all readers. Lastly is a topics list that can help show some specific concepts that are covered in the article.

New in the format is MY comments at the start of each article. You can tell it's me, because they have my initials at the end (BDK). This way you get to read what I hope is some specific information that will get you off to a good start reading the article.

The articles are good as always. TCJ has many excellent writers and this issue is no exception. I have pressed some new people into covering some different topics. For comments from the editor, other than a quick review of what is inside this issue, you will need to check out my Computer Corner, where I have been making comments on many topics for over 8 years (hard to give up the old ways.)

Other than our feature, which is a must read for everyone, we have Jay Sage, Tim McDonough, Frank Sergeant, Tilmann Reh, and our surprise new writers. So set back and check out the issue.

## Reader to Reader

Dear TCJ:

I have gotten one of your free issues and have decided not to subscribe. I work for a small company and had hoped you would help me get up to speed with new microcontroller construction projects. So far it looks like everything is way over my head. I need beginner and refresher information. Sorry, but thanks for the freebee.

-John Clark, LA, CA.

*Thanks for the letter John, and you will get this and one more issue. The reason is our change of ownership and some minor correction of course. You see John I have been well aware that we have not been covering the beginner for some time now. I feel that even experienced people start out on new projects as beginners as well. So when ever we start a new topic from now on, we will try and cover it from a beginners view point first. We can not however teach you everything about electronics, so I will assume you have had at least a few basic courses in electronics and know what end of a soldering iron to use. I have heard that most of the competitors have refused to print beginners articles, NOT HERE. I teach at a junior college and have learned how hard it is for most people to get started on new projects. That is another reason I am trying to do "Platform Independent" projects. The simpler the project the better chance you have of learning. Please write me again if you have topics or suggestions about projects that would make you a confirmed TCJ reader.*

-BDK

Dear TCJ;

I don't know how to write an article about my YASBEC, but I can write a letter, so here goes.....

You probably have already looked at the pictures I sent, so maybe this will help orient you. The case is Hewlett-Packard surplus I paid about \$5 for. (I keep forgetting prepositions are things you're not supposed to end sentences with!) The case housed a power supply, I think. Outside dimensions are about 5 1/2" x 8 1/2" x 13 3/4". Front and back aluminum castings are connected with removeable rails. There are top, bottom and side removeable covers (detach with one screw). The back panel already had the ac power receptacles, switch and fuse, and it was a simple matter to cut the openings for the parallel and serial connectors. The 5 1/4" Mitsubishi 40 track drive attaches with screws to the bottom of the case, the two TEAC FD235 3 1/2" drives are stuck to the 5 1/4" drive with several thicknesses of double sided (removeable) foam. The YASBEC board is stuck to a thin plastic panel also with foam pads. The thin plastic sticks to the top of the 3 1/2" drive. Power is obtained from a 150 watt IBM Clone removed from its metal case. 1/8" deep by 1/8" wide vertical slots in the side rails near the rear of the cabinet allow the power supply board to fit neatly, allowing enough room at the sides for ribbon cable to the parallel and

continued on page 3

serial connectors. On the left side of the cabinet I mounted a Rodime .45 meg 3 1/2" hard drive, attached to the horizontal rails. I also placed a small (2 1/2") 12v fan behind the hard drive. The fan may be unnecessary since the perforated covers allow much ventilation. The front of the panel is filled in with a bit of gold colored perforated aluminum cut to fit around the drives and holding the reset button and pilot LED.

Everything works well except the hard drive. That appears to be a BIOS problem and I am hoping the new banked bios will take care of that.

A bit of history.....I first learned about YASBEC in the TCJ editor's note in TCJ #50 and in Z-Letter. I watched with interest the TCJ and Z-letter references, then in the late summer talked with Paul Chidley on the phone. Didn't take the plunge until late fall then sent Paul my check. All the info on Genie and Zcentral was helpful in gathering the components. Ludo Hemelryck supplied the Z180, SCSI and some sockets. Once I had all the parts it was a breeze soldering them in. As far as I could tell there were no solder bridges or cold joints. My only error was to rotate the scsi socket 90 degrees. But the error was spotted and the socket modified with my dandy little Dremel Motortool. (Later I removed and replaced the socket.)

Then everything was hooked up. I turned on the power.....NO SMOKE. Hooked up the terminal, but nothing on the screen. It wasn't until Ludo told me to hit return a few times (and at last I perused the documentation)that I was able to get the screen display. About that time I received the BIOS disk from Cam Cotrill. At first I couldn't get zcnfg to work. It turned out my junkbox 5 1/2" drive was bad. With a decent drive it booted fine and I was able to configure the 3 1/2" drives. All this time the whole thing was only haywired together. I was moving the main board around when suddenly..... A small puff of smoke toward the front of the board!!!! And all was gone.

Surely after all this my YASBEC couldn't be dead! But it was. I later learned I had

been Albany'd. It seems the 5 volt supply on the board has a trace (hidden under a ram socket) that acts as a fuse if vcc is shorted. Paul Chidley told me about that. It seems a soul (who shall be nameless) from Albany NY had inadvertently done the deed I did. I am also from Albany (Oregon). Not knowing about the New York incident I thought Paul was ribbing me. Each of the states of Georgia, California, Illinois, Indiana, Kentucky, Louisiana, Missouri, Ohio, Texas, or Wyoming also has an Albany. I wonder if anyone there has put together a YASBEC!!!!

At any rate jumpering the burned trace put everything straight again.

Most Z software I have tried so far works. I'm using a Televideo 970 Terminal. The extended tcap for the 970 is almost right on screen graphics. I haven't yet found out why LSH doesn't work. Since I plan to go to Trenton in April I'm hoping to get some help.

To summarize my experience - 1) the YASBEC is a great little board 2)it went together easily 3) except for the hard disk everything works great 4)the folks in the 'Z' community are most kind and helpful. I trust this gives a hint of one YASBEC users experience

Yours Sincerely  
A. A. Straumfjord, Albany, OR.

*Thanks for the letter and pictures. Sorry I couldn't get the pictures in this issue. With all the changes, I am not ready to put pictures in yet, maybe next issue. Glad to see that some are doing and succeeding with projects from our pages. Maybe if you learn some more about constructing, you can give us a beginners eye view of what type of problems you overcame to make it work. How about it? - BDK*

Dear TCJ:

I am a regular reader of the Computer Journal, either by subscription or second-hand. I also see you on the CPMTECH Fido echo occasionally. I am pleased that you continue to support small developers and "classic" development environments and tools. To further those

goals, I'd like to offer you an article or two that suggest yet another developers' strategy that combines low cost, familiar technology, flexibility, and support for Zsystem/Z80/Zx80 technology.

For several years I have worked with, bought and sold S-100 equipment. As an electrical engineer and programmer in the 70's and '80's, I often found these systems operated by my industrial clients as well as in the basements of my engineering colleagues. Today, I still find them in use among many technologists, both experienced and new; as well as in flea markets, basements, and Salvation Army stores. Many people still refer to the IMS AI, with its front panel and blinking lights, with affection.

As you know, there is a resurgence of interest in Z-80 based systems due to development in new operating systems (Z-system, et. al.) and new, faster, and expanded Z80 processors (Z180, Z280, Z80XXX I/O processors.) Yet it is relatively difficult to work with these processors and systems given the almost overwhelming influence of the MS-DOS world of cheap, fast, available 80X86-based computers: computers that are also hard to program at the 'nuts and bolts' level. I believe I can offer a better alternative to your readers.

S-100 systems (or IEEE-696, an ANSI standard) can offer a very affordable platform for Z80 development. In fact, almost any processor can run on the S-100 bus (and many have!). While the speed of older designs was limited to 2-4MHZ, and the very oldest boards were limited in both speed and memory capacity: there are still many cards, built in the 80's, that have modest amount of memory, I/O capability and flexibility.. More to the point, they were built on LSTTL chips that are readily available, quite rugged and - a big plus- well understood and documented. Given also that many S-100 boards have descriptive information printed on the board themselves, even boards purchased without documentation can be "deciphered" with a few evenings' work: an educational exercise in itself! Finally, cost are reasonable to free. A typical disk-based system sells - working and documented

- for \$50 to \$200. Undocumented and "orphaned" systems, about to be discarded, can often be had for the asking! I have already published two articles on the pre-IEEE S-100 bus in the Z-letter, which I hope will represent my writing ability and technological knowledge. I propose a short series of articles to introduce the possibilities of S-100 development systems as a cost-effective and easily-learned environment, culminating in a Z180 processor card design. The Z180 processors appear to be a "small stretch" from Z80's both in cost and capabilities, and more than adequate for most uses.

Regarding my own interests: As a reseller, of course, I am interested in encouraging sales of my various used cards (catalog enclosed). My experience suggests that my prices are not out-of-hand for the card replacement market; and I have priced many cards below those levels. The replacement market seems to be limited to Compupro/Cromemco owners who have strong commitments to maintaining systems: and even they are now 'bailing out' at the few hundred dollar level. Meanwhile, I have many cards that are not purchased often: 16K static RAM cards, bank addressable and otherwise flexible; serial/parallel cards; and 8" floppy disk controllers. For developers and experimenters, these are still cheaper than the 'single-chip solutions' and software that would replace them. An article on evaluating and adapting these cards, written in a methodological fashion for general use, would help ALL those people who are trying to get a system up without documentation. Finally, your vendors can provide Z-system software, and I can provide CP/M 2.2 for about \$25.

In summary, I propose a series of articles as follows:

"S-100 Systems: The Final Frontier" would introduce S-100 and IEEE-696 systems as stable standards for small processor development. They are widely available, terribly economic, and suffer only from "old technology" (actually an advantage) and lack of documentation

(a "learning situation" with the right tools and information).

"Buying and Fixing Your S-100 system" would describe the history of several S-100 manufacturers; suggest the best kinds of boards and systems to buy, and offer tips, techniques, and general manufacturing practices that can aid in debugging and testing your system without elaborate tools and technology. This can easily be two articles! Given that there is two months between them, however, I would like to encourage both purchase and experimentation early in the series.

"A Z180 for the S-100" would describe a straightforward design of a Z180 processor card with on-board static memory and serial ports, which would drive either the S-100 bus (briefly, two 8-bit data paths, and 16 bits of address) or the IEEE-696 bus (8 or 16 bit data paths, 24 bits of address).

So what do you think? Contact me promptly: obviously this is a significant commitment on my part, and I need to plan for it as soon as possible. Please send appropriate information on writers' guidelines and your general comments. Thanks for your efforts and interests!

Herb Johnson, Trenton, NJ.

*Well herb that was some letter and I couldn't have said it better. I have been a long time user of the S-100 systems and in fact still have several running units. That catalog was missing and hopefully you will send me one soon.*

*What the S-100 systems reminds me of is when people were just starting to become electronic technicians, a normal approach was tearing apart and repairing old TVs. Well today, the modern computers have nothing that can be fixed or tinkered with in them. I have been thinking of doing some beginners and learning articles on using the S-100 products as the basis of building the readers skills. I will be calling you soon and dropping in the mail the writers guides as well. For our readers information then, you can expect to see some of*

*Herbs' work in up coming issues. Please check over the Back Issues section of the magazine and you will find we have done many S-100 articles over the years. In fact I though we had already done a Z180 S-100 construction project as well.*

*Having written several of the past S-100 articles, and cut my teeth on them, it will be like old times to run your articles. And by the way, do you happen to have CP/M 68K for a Compupro CPU68K? As far as documents, I would like to point out to our readers that I and many of our readers have hung on to our old manuals. So if you are having troubles getting one of those S-100 systems running drop me a card and if I can't send you copies of what you need, I will at least put your request in the Reader-to-Reader section. If we get enough request for "orphan information", I will set aside a special section and maybe ask Herb to be our Doctor S-100. Now that request for literature can be for systems other than S-100 as we have readers who still use all types of non-PC products. BDK*

#### Reader-to-Reader

To send letters to TCJ, mail them to:  
The Computer Journal  
P.O. Box 535  
Lincoln, CA 95648-0535

The editorial policy is to try and print your entire letter "as is." TCJ however does reserve the right to reject and or modify (by omitting) portions of letters deemed unfit for publication.

Major letter and minor articles are accepted on floppy disk and will aid in getting your letter published "as is." TCJ does not return disks and material, unless suitable and appropriate return mailers are provided.

Floppy disk and word processor formats supported are all the generally accepted programs (I.E. Wordstar and WordPerfect) as well as any format acceptable to PageMaker 4.0. CP/M formats are supported through use of a CP/M to PC DOS disk format converter. Currently no 8 inch disk formats supported (later maybe.) GENIE mail checked on regular basis (use B. KIBLER.) Other bulletin boards and services will be added as time permits.

---

# The Computer Journal - The next TEN years Feature Article

By Bill Kibler Editor/Publisher

All Readers

Future of *TCJ*

---

---

**When** issue 60 rolls of the press at the end of this year, The computer Journal will mark ten full years of "howto" articles. It seems as if it was a short time ago that I wrote that first TCJ article. I have in fact been writing for TCJ practically the whole time and plan on continuing to do so. What the next ten years will bring in computing I have no clear ideas. What TCJ will bring to you I want to talk about.

## THE BEGINNING

When Art Carlson started The Computer Journal, it was mainly an outlet for do it yourself hardware projects. Art had many projects he wanted to do, and felt that other would want to know the results of his endeavor. My first article for Art was on upgrading 16K memory cards to 64 and 256K. Another article was on adding a Centronics interface to a Z80 system. Many smaller hardware projects followed as well as the software to support those changes.

I would say those first few years, saw equal amounts of hardware and software features. We also added industry and machine specific columns to help keep our readers abreast of changes that might effect them The main focus were hardware "how to" articles. We have changed some over the years and I am not sure for the better.

## THE NOW

The industry as a whole has moved away from "doing hardware." TCJ has been influenced by this change as well. The influence of the PC with easily assembled hardware and low price have made hardware hacking a thing of the past. The big caveat is that hardware is and always will be needed, and some of us love to tinker. As a HAM radio operator I got started by building and modifying transmitters and receivers. In

college I studied solar system design and intended on using computers to control solar house systems. At that time microcomputers were just becoming available and my love of tinkering put the two together.

The modern PC clone is no longer a box to tinker with. The operating system and software needed is so complex the supporting documentation stands over three feet tall. It is not the machine for people to leant on and have fun with. When it comes to doing writing and design the PC works just fine. I think it should stay that way myself. So what has happened to TCJ over the years has been getting caught up in the PC clone hardware mess without intending to do so.

TCJ has had many hardware articles, in fact Chris McEwen got Frank Sargent to give us his award winning RTX system. That was a non-PC clone hardware and software project that given the time I will build myself. I can build that project because I happen to have an RTX contest board What if you don't have one however and what about the RTX chip itself?

## THE NEXT TEN

Over the next few issues and on into the future, TCJ will be making a few minor changes. I plan on taking the magazine back to our "ROOTS". With that I mean more articles on hardware. More how to do it articles for people of all experience levels. One problem with that approach is usually the platform of choice. My choice is NONE! The articles will be "platform independent". That means they must be projects based on serial or parallel ports, if not standalone.

My requirements do not stop there. No PALS or specific vendor devices allowed. These projects must be possible to build in

any garage anywhere in the world that has access to standard computer parts. For the software side, I will stress FORTH as the language. Forth is the only true platform independent language around. The articles will however have other languages, especially assembly when needed The article will help guide and show the reader how to do it the most efficient way possible. Pseudo code or flow chart like coding will be used so that each reader will be able to convert the given code to a language of their choice. TCJ will not be another "C" only magazine.

## Market Standing

The Computer Journals standing in the market place will be somewhere between Circuit Cellars INK, Elektor, and Midnight Engineering. In reviewing those issues, each has something for our readers. They also have points of view or positions that make them less effective for our readers. Take Circuit Cellars INK for example. The magazine's focus is on selling Micro Mint products which are almost always based on Intel products. Currently they feature wiring the house with Micro Mint systems if you want to be "in with the electronic cottage."

Readers of Midnight Engineering appear to be hopeful business people. The magazine header is very clear about their support of people wanting to make a business out of their hobby. There are some very good articles on hardware and software, but business articles are their main stay. I am not sure that our readers are so business directed that they want business articles in place of more how to hardware articles. I feel that many of our readers are using computer products to sell and service non-computer based products. They know their business and how to package it, what they

need is how to save money using this system or that process.

Elektor magazine is new and very close to my idea of what level of support we should be providing. The problem with Elektor is they also support radios, antennas, audio amps, and computers. That broad approach is fine unless your interests are only learning how to use stepper motors. Why pay for a magazine that only has one article an issue of interest to you.

What my hope for TCJ is that we can provide the reader with a full issue of important and interesting articles. To that end I propose trying to have a 30% ratio. I want a third of each issue to support old or recycled systems. Many of our foreign readers (15% of our subscribers) don't have access to the latest systems. Currently no other magazine supports Z80, S100, or ZCPR users. We will continue to provide regular and special articles for those users.

The next third will be on hardware and software projects (more hard than soft I hope) that are platform independent Serial and parallel projects that will lead the reader through the steps of building and having a useful device in the end. Like most magazines we will try to provide either bare boards or complete kits for those without access to the materials used. I have had several requests for stepper motor how to. We have talked about steppers in the past, but too much space was put on software and not enough on the hardware. The person who pointed this out had blown up several stepper motors before giving up completely.

The last third will be on reviewing products and services important to our readers. I have often complained that Forth Interest Group never reviews vendors of Forth. If your starting to look for a Forth that will help you talk to remote door openers, whose is the best, or do I roll my own. Now reviewing has its' problems, as you can appear' to represent one or the others product. Our method of reviewing will be two fold. First I will let the vendor explain the why and wherefore of their product. This will include some examples from their manual (usually the tutorial section). Then I will find someone not related to the vendor and ask them to try the tutorials and

produce some real results. That will take several articles to cover, but by the end all the good and bad points should be clearly visible. The object is for TCJ not to give an opinion on the product but to give you enough information to make up your own mind. What are we going to review, I got two items to start with, embedded controllers development packages and CPU trainers.

One main issue that TCJ will continue to press is keeping things affordable. Our aim will be to make The Computer Journal the most cost effective magazine you receive. We will do that by putting more articles that you can use and build Those projects will also be as inexpensive as possible. Recycling of systems will be one strong point of hardware projects.

#### The Next Step

At this point I need to move on to being more of an editor than writer. The next

issue of TCJ is starting to come together and as such I must put off more comments on TCJ's future. As readers and supporters of TCJ, you can continue to express your thoughts about where we need to go. I always look forward to reading and publishing your comments. These minor changes and TCJ's next ten years are really the choices of you, the reader. Without your input TCJ will be unable to continue it's growth. We have doubled in numbers from Chris's work and maybe we can do that again with this improved focus. Let me know what you think.

As always TCJ can be found on GENIE as "B.Kibler" and a answering machine is standing by 24 hours a day for your subscription or comments. The new address for your correspondence is P. O. Box 535, Lincoln, CA 95648. That phone number is (800) 424-8825, or (916) 645-1670.

### UNIVERSAL MICROPROCESSOR SIMULATOR/DEBUGGER 2.0

- Simulates the Z80,8051,8085,6811,6809,6805, 6801,6800,6303,6502 & 65CO2.
- Cross Assembler and Disassembler.
- Accepts Binary, Motorola, and Intel Hex codes.
- **Windowed source-level Debugger.**
- Handles exceptions simulation.
- Includes batch file capability.
- Utilizes your PC's I/O for MPU simulation.
- **\$90** each set.

### THE ROMV-8 EPROM EMULATOR

- Works with CPU simulator (Exclusive Feature).
- Lets you change and test code in seconds.
- Monitors address bus.
- Patch code with assembler.
- Emulates 2716-27256 EPROMs.
- Loads 32K of code in 20 seconds (PC/AT).
- 90 day warranty.
- Saves you money - only \$155 (complete with one set of CPU simulator).

# INPUT EXPANSION FOR 8031

By Tim McDonough

Embedded Systems

Beginners and up

8031 Construction

---

---

*Tim's article this time is a simple hardware method to get more I/O for your system. It is based on his 8031 system he sells, but the technique is definitely PLATFORM INDEPENDENT. As you will see he uses a chip I have seen in the books many times but never thought to use it in this way. Great idea Tim, BDK.*

Digital inputs in a microcontroller system are like disk space on your PC or vacation days at the office -you can never have too many of them and, more often than not, things would be better if there were just a couple more...

Are your projects like many of mine? Do you often wish that all 40 pins on an 8031 were inputs? Having every pin as an input port may be impossible but there is a method you can adopt that will let you stretch 4 of the existing I/O lines to nearly as many digital inputs as your system will ever need.

The traditional method of adding digital I/O to many microcontroller systems is the addition of an 8255 Programmable Interface Adapter (PIA) into the memory map of the system. The 8255 is addressed as RAM and provides 3 bi-directional ports of 8-bits each for a total of 24 additional I/O lines in your system. It is a very reliable component and is well worth considering for many applications.

There is some downside to the 8255 style of I/O expansion, particularly if what you need are more input lines - it is a memory mapped device. If your system requires a large amount of RAM several ICs or a Programmable Logic Device (PAL) may be required to decode the PIA into the smallest amount of memory space possible, thus preserving

the maximum amount of space for system RAM. In other applications the circuit board space and the cost of the extra decoding logic may be unacceptable.

My digital input expansion example requires 4 of the 8031's I/O lines to provide any number of additional digital inputs. A little software overhead is required but the advantage is that whether you need 8, 16, 24, 32 or even more inputs, this method only requires 4 of the MCU I/O lines leaving as many as 10 lines free for outputs or special purpose inputs if you don't require a serial communications port.

The key to the design is the 74HCT165N Shift Register. This IC is a parallel-in, serial-out register that easily converts the digital inputs in a system to a serial bit stream that can be collected by the 8031. Inputs and outputs on the '165 allow them to be cascaded to provide any number of inputs subject to the fan-in/fan-out limitations of the LOAD, CLOCK, and ENABLE lines that are bused together.

The project is based on my Control-R I Single Board Computer (SBC). It provides the core components used for many 8031 designs. Major components include an 8031 MCU, address latch, EPROM socket, and MAX232 to provide an RS232C compatible serial port. Serial communications routines for the 8031 have been presented in other TCJ articles and have been included in the source code for the system I'm presenting here.

The 8031 has a total of 16 digital I/O lines available for general purpose use. Most of my applications use the serial port which requires a minimum of two

of the I/O lines on Port 3 (more if hardware flow control is required.) If the system includes external RAM or other memory mapped devices, two additional lines on Port 3 must be used for the \*RD and \*WRITE signals. The bottom line is many applications require a lot of digital inputs. Configuration switches, operator controls, sensors, etc. can rapidly consume the remaining 12 I/O lines before your project gets too far off the ground.

Figure 1 shows a schematic diagram of a pair of 74HCT165N shift registers that I've attached to the basic Control-R I SBC. These two registers provide the demonstration system with 16 bits of digital input. Additional 74HCT165Ns may be cascaded to add more input lines as desired. Note that each shift register input has a 10K pullup resistor. These pullups are mandatory to force each input into a stable condition (logic "1"). Failure to include them in your design may have disastrous effects on your system.

In many systems it may not be strictly necessary to use the ENABLE signal. If the shift registers were the only circuitry attached to the lines used for DATA, CLOCK, and LOAD it could be tied to ground, permanently enabling the registers. I prefer to control it from the 8031 so that I can use the port pins assigned to DATA, CLOCK, and LOAD to other functions if needed.

Programming the shift registers is quite straightforward. Listing 1 shows the complete source for the application. The essential steps in moving data to the microcontroller's memory are as follows.

1) The ENABLE line of the shift registers is brought low.

2) The LOAD line is briefly pulsed low to latch the data present on the parallel input lines into the register

3) For each input line present, a positive going clock pulse is applied to the CLOCK line and the state (high or low) of the DATA line is read and processed by the 8031 using one of the bit test instructions.

4) The ENABLE line is brought high, disabling further control of the shift register.

The SHREG and READ8 subroutines are the key pieces of code for reading the shift register data. SHREG enables the shift registers and loads data into the shift registers. Next, for each shift register in the system, the READ8 subroutine is called. READ8 returns the eight bits from a register packed into a single byte that is returned in the Accumulator register. After each call to READ8, the SHREG routine stores the returned data in memory for later use.

The READ8 subroutine is easy to understand once you walk through it a couple of times. It starts by loading the number of bits to be read from a single shift register into RO (Register 0) which is used as a counter. Next, the clock line attached to the shift registers is pulsed high to shift one bit of data onto the DATA input to the 8031. The next step is to clear the 8031's "carry" flag in preparation for processing the bit.

The bit test is done with the 8031's JNB instruction. The DATA line is tested. If it is "low" or logic zero, program execution jumps to the code at label 'READ82'. If it was "high" or a logic one, the SETB (Set Bit) instruction sets the value of the carry flag to a logic one. At this point my program has set the carry flag equal to the value of the DATA line.

The next step is to move the data that's been stored in the carry flag to a temporary variable that is used to hold the other bit values as well. First the temporary data is copied into the Accumulator. Then a RLC (Rotate Left with Carry) instruction copies the bit that was stored

in the carry flag into the least significant bit of the accumulator. All other bits in the accumulator are shifted one to the "left" as well. Finally, the current value is placed back in the temporary storage location RI (Register 1).

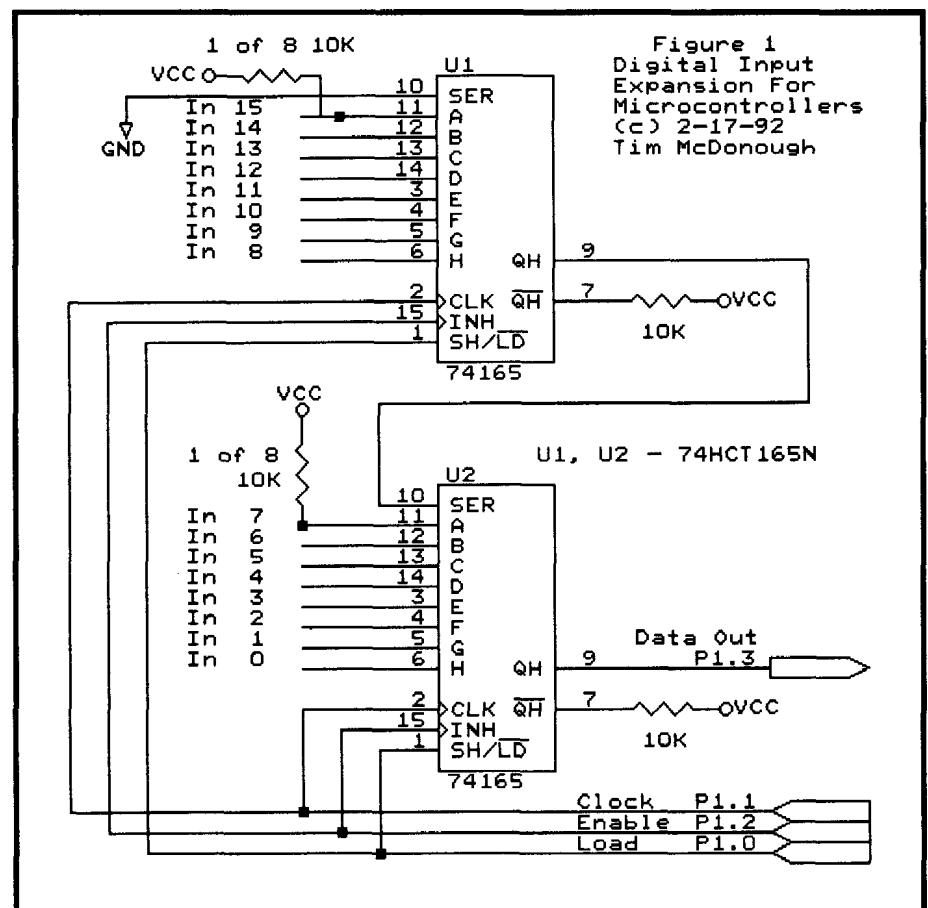

Once a bit has been inspected and stored in the temporary variable RO is decremented and tested. If it's not equal to zero, meaning all eight bits haven't been read yet, program execution jumps back to label READ81 for the next bit. If it is zero, all eight bits have been read. The temporary value is copied into the accumulator and the subroutine returns.

The remainder of the program in Listing 2 should be old hat to experienced 8031 programmers or those of you that have read previous "Embedded Systems for the Tenderfoot" articles. Each time the command string "@A" is received at the serial port, the 16 digital inputs are read and stored in two one-byte memory locations. The data collected is then converted into printable ASCII form and transmitted back to the host computer as 4 hexadecimal digits.

While testing and debugging the hardware and software it can get very annoying to constantly have to run a terminal program and type "@A" while trying to measure what's going on in the circuit. To simplify my life (isn't that what computers are all about anyway?) I wrote a short program in Microsoft QuickBASIC Version 4.5 that polls the Control-R I for data once a second. The source code for the test program is shown in Listing 1.

I hope this latest installment in "Embedded Systems for the Tenderfoot" has peaked your interest. If you have questions or would like to see a specific topic covered in a future article please drop a note to TCJ and we'll see what we can do. I won't promise to do your next design project for you but I'll try to cover things that may be of general interest to developers just getting started.

For those of you who hate typing or who don't have access to Microsoft QuickBASIC for the test program, I'll make your life easy. If you live in the US or Canada, send a \$5.00 (US) check payable to "Cottage Resources Corporation" to the address below and I'll send

you a 5.25" 360K MSDOS disk with the SHIFT.ASM source code, the compiled QuickBASIC test program, and some other assembly language odds and ends thrown in for good measure. Please indicate the check is for the SHIFT.ASM disk and include your return address. You cannot order this disk from the Sandy, Utah office and we will not accept credit card orders for it.

*Tim McDonough is a network engineer turned electronics entrepreneur. He may be reached at the Midwest offices of: Cottage Resources Corporation Suite 3-672,1405 Stevenson Drive Springfield, IL 62703 (217) 529-7679*

```

PROGRAM:      SHIFT.ASM
REVISION: 1.1
DATE: February 17,1992
AUTHOR:      Tim McDonough
Cottage Resources Corporation
This program demonstrates the use of parallel-in, serial-out shift
registers to expand the input ports of an 8031 microcontroller. This
example uses two type 74HCT165 integrated circuits. By adding
additional shift registers and increasing the buffers and clocking any
number of inputs may be added while still requiring only 4 MCU lines.
; In this example program a host computer sends a command to the 8031
; that causes 16 external inputs to be read and stored in internal RAM.
; The two data bytes are then formatted as printable hex numbers and
; transmitted back to the host computer.

## Regular Feature

### ZCPR Support

## Some General Thoughts

# The Z-System Corner

By Jay Sage

*I was able to talk to Jay just before he left for Europe. I had just finished "The Next Ten Years" article and faxed it to him. I think it was too much too fast for him. Sorry Jay, but I have been thinking about these changes for some time now. Jay pulled through and managed to give us some of his wonderful insights into a DOS program (from a lover of 8-bit systems no less - what is the world coming to,) BDK.*

By now you are aware that TCJ has a new editor and publisher. During the period while TCJ was in transition, no one was enforcing submission deadlines. With no deadline, it was natural for other pressing tasks to come to the fore, and as a result, two days before I depart for my annual vacation in Germany I have no column ready!

I have a long list of things I want to talk about in TCJ, but there is no time to work out one of my usual complex, technical articles. So this is going to be a short, chatty column. At first I thought about just skipping an issue, but I have a strong commitment to tradition, and in the end I could not face the pain of breaking my uninterrupted series of columns going back to issue 25, more than five years ago.

### Zed-Fest Europe 1992

Last year during my vacation I had the pleasure of participating in an exciting meeting that was organized by Helmut Jungkunz and Uwe Herczeg to bring together some of the most active 8-bit hobbyists from all over Germany (and elsewhere, too). Thus was born the first European Zed-Fest. We all had so much fun that we are doing it again this year.

In one of my TCJ columns last year I gave a sketchy description of last year's meeting. This year I am going over better prepared. I've even bought a roll of black-and-white film so I can take some pictures for publication. During the past month, whenever I exchanged Internet mail with Europeans, I

have invited them to come to the Zed-Fest. As a result, I hope we will see some new people there this year. In my next column you can expect a thorough report.

### 4DOS: Z-System for DOS Computers

In my last column I already wrote enthusiastically about 4DOS, the ZCPR3 of the DOS world. If you can believe it, I have gotten another factor of 10 more enthusiastic since then. Just as Z-System enormously increased my productivity on 8-bit computers, so 4DOS has revolutionized my use of my DOS machines. Thanks to 4DOS facilities and the PMATE text editor, I expect to be busy at the office simulating a new circuit concept the whole time I am on vacation! This is even better than telecommuting. I'm going to let the machine do all the work for weeks on end while I relax in the mountains of the Black Forest.

The powerful flow-control facilities in 4DOS together with the extended environment variable functions will make it possible for my 486 computer to perform a complex set of SPICE circuit simulations to determine the parametric margins of a new circuit I have invented. A set of PMATE editing macros examines the SPICE output file and determines whether the circuit performed correctly or failed in some way. PMATE and 4DOS maintain a number of log files with summaries of the progress and results of the calculations. PMATE also writes information out to files that 4DOS can read to determine how to vary the circuit parameters. 4DOS can then conduct an efficient search for the parametric limits within which the circuit can operate. When I get back I expect to find a file with a concise summary of these results.

One new twist that I have to implement is power-failure recovery. We've been having lots of trouble with the power substation that supplies Lincoln Laboratory, and I have to expect at least one power failure while I am away. This means that I have to provide some way for 4DOS to save and restore its

state. When the power comes back up, the computer has to restart the batch file and pick up where it left off.

I don't know if all this is going to come together before I leave, but I expect to give a report and describe the techniques I use in future issues of TCJ. Although this particular application is running on a DOS computer, the techniques apply under Z-System as well, and I use them regularly, albeit on a smaller scale.

### Meeting the Author

Yesterday I stopped off at the offices of JP Software in nearby Arlington, Massachusetts, to meet with Tom Rawson, one of the two principal authors of 4DOS, along with Rex Conn who works out of a Washington office. My purpose in making this visit - besides getting to meet someone whose work I so respect - was to show them a few things that we do in Z-System that 4DOS does not yet do. The two main topics were error handling and the full-screen history shell capabilities of LSH. Tom was impressed, and I hope we will see some advances in this direction in a future release of 4DOS.

Everyone in the JP Software offices was unbelievably friendly, warm, and helpful. Tom agreed to meet with me prior to my departure for Europe even though a maintenance release of 4DOS was due out that very day and he had not quite put the finishing touches on it yet. Although we were talking about DOS, it felt like a meeting of Z-System enthusiasts. Not only does 4DOS - the product - have a Z-System feel, but so do the people involved in its development. I felt a strong sense of kinship. I really wish them well and hope that all you DOS users reading this column will purchase the commercial (or, if you prefer, registered shareware) version of 4DOS.

Have a nice summer everyone.

# Connecting IDE Drives to 8-Bit Systems interfacing Systems

By Tilmann Reh

Intermediate Skills

8-Bit Construction

---

---

*I recently went to a IDE drive on my own system. Since then I have been wondering about their technical side. Although Tilmann is interested mostly in their 8-Bit data usage, the information presented here will help with any system. So Tilmann can I hook this to my NOVIX system? Read on and see for yourself. BDK*

Most of us know about the features of a hard disk compared to floppy disk operation. You get much higher storage capacity while dropping access times down to a few milliseconds. Before installing a hard disk, I was used to copying all files for the current project to the RAM disk of my CPU280 and then copying all changed files back to floppy when I was finished working for the day. Although this is much better than working with floppy disks only, it is not comparable to using a hard disk. With a hard disk, you just work on your projects, which can now use files that would not fit on a floppy or RAM disk, and you don't have to copy files around the drives. In addition, the access times are almost as fast as those of a RAM disk. Last but not least, you are freed from changing floppies like a D.J., since all files are accessible without mechanical action on your part.

## The Technology Decision

When thinking about connecting a hard disk to a given computer system, the main decision that must be made is which interface technology should be used. The old ST-412/506 interface is not up to date (I think it is impossible to buy new, small drives with that interface), and the hardware expense for this type of controller is great. Additionally, these con-

trollers have some critical analog circuits which have to be adjusted very carefully.

The next technological step was the ESDI interface, which is quite similar to ST-412/506, except that data is transmitted in parallel and with higher (but still fixed) data rates. The ESDI controllers are more complex and the drives more expensive than the ST-506 components. So ESDI is not interesting for our use.

The SCSI interface is a universal peripheral interface that is often used for hard disk connection. Some machines (Apple Macintosh, NeXT) even support no other interface for this purpose. SCSI is a very powerful and good interface, and SCSI drives are well established and available at acceptable prices. For the host interface (that is the controller) there are some chips available that do the complete bus protocol work in hardware and software and deliver raw data for the host processor.

Another alternative is the IDE interface (also known as the AT Bus interface). This interface is used in almost all IBM clones these days. Like the SCSI drives, the IDE drives contain the complete hard disk controller on the drive (this is where the name comes from: IDE means "Integrated Drive Electronics"). But these drives are connected to the standard PC-AT bus system and are accessed just as with the normal PC-AT hard disk controller. So, in effect, you don't need a controller any more but just some interface electronics that simulates an AT bus. The IDE drives are slightly cheaper than similar SCSI drives, and since the interface is simpler, I chose this one for my project.

However, it must be said that this decision was made with only the hard disk connection in mind. If someone wants to connect more peripheral devices (i.e., scanners, CD ROM, etc.) or more than two hard disks (which is the IDE limit), the SCSI interface is preferable (one interface for all devices).

## The Interface Circuit

The greatest problem when interfacing an IDE disk to an 8-bit computer system is the differing bus width. While the control registers of the IDE drive are still eight bits wide, the data transfer is done word-wise (16 bits each transfer). So we need an interface which maps the 16-bit data register to the 8-bit bus.

There are two basic approaches to doing that. The first (and easiest) one is to map the two halves of the 16-bit data into two different I/O addresses. The strobe for the IDE drive would have to be generated with the read signal for the lower half and with the write signal for the upper half. The control registers would then be accessed by always reading the LSB and writing the MSB. However, although only simple hardware is required, this method has a very great disadvantage: since two different I/O addresses must be accessed alternately, you cannot use string instructions (such as the Z80 INIR/OTIR) or a DMA controller for data transfer. Thus, the transfer rate would be relatively slow and the programming not very elegant.

The other approach is to map the 16-bit data onto two consecutive accesses to the same I/O address. This way, some circuit expense is necessary to switch the right data halves to the data bus and to

handle the 8-bit accesses to the control registers. However, with this slightly more complex hardware, we get great software advantages. With this technique, using string instructions or DMA is the normal way to transfer the data to or from the disk drive.

Of course, we need some circuitry to remember which half is to be processed next, in order to select the correct data path and generate the correct strobes for the drive. As we have to distinguish only two cases, one flip-flop is enough. Since I planned to use a GAL (generic array logic) for address decoding and bus interface anyhow, I used one of the GAL macrocells to make the flip-flop. The clock pulse for the flip-flop is generated each time any register is accessed, and the data is set to zero when other than the data register is selected. This way, accesses to any control register also reset the state flip-flop, thus ensuring proper conditions when the data transfer is started.

The rest of the interface circuit is self-explanatory: one half of the 16-bit data is always processed directly, while the other half is stored in a latch or register. For the control registers, the latch becomes transparent. The strobes and select signals for latches, buffers, and drive are generated with the GAL mentioned above.

### Slack Space On Board

The IDE interface itself would easily fit twice (or even three or more times) on a standard EuroCard-sized PCB. To avoid wasting board space, I filled the free space with some useful circuits which would serve the CPU280 very especially well but also make sense with other systems. The first additional circuit is an active termination for the complete ECB Bus, which is absolutely necessary with bus clocks of 4 MHz or more and a backplane of some length. With still more space left, I added two control buttons for hardware reset and NMI (non-maskable interrupt) generation and four LEDs as a power-control monitor. Last but not least, I finished the design with a Centronics-type parallel printer interface. The decoding signals for this interface

are generated using components that were already there for the IDE interface, so this involved almost no additional circuit expense. Of course, if someone needs only the IDE interface, they can just leave the rest of the board unused!

### How To Get One

If you are interested in the interface, I think it will again be the best to contact Jay Sage for the availability of PCBs, programmed GALs, driver software, etc.

*Tillmann Reh is an electronic engineer at the University of Siegen, Germany. He also owns a small company that develops custom solutions using embedded controllers or microcomputers. Tillmann has been active with CP/M since 1983 and developed a number of ECB-bus boards. He can be reached by regular mail at Tn der Grossenbach 46, W-5900 Siegen, Germany'or by E-mail (international/bitnet) at 'tilmann.reh@hrz.uni-siegen.dbp.de'.*

## 8 Queens in Forth

by Frank Sergeant

*I need to thank Frank for putting 5 copies of his story on the disk he sent me. The post office managed to mangle the disk so bad that 4 of the 5 stories were unreadable. Only the inner most story was still undamaged. I had to take the envelope apart and use it on the bottom half of the jacket. After all that it made reviewing his article a joy. As always Frank's solutions to age old problems makes reading damaged disk seem like child's play. BDK*

It all started when a correspondent mentioned he was converting the code for the 8 Queens problem from Fig Forth to Pygmy Forth and adding trace routines to try to make sense of how it worked. It so happens that the 8 Queens problem had been discussed and assigned a few weeks earlier in the data structures course I was taking at the local university. The course work had to be done in C, but I first worked out the solution in Forth as its interactive nature and quick response make it easy to try out various ideas and approaches. Henry was working with the version of 8 Queens written by Jerry LeVan that appeared in Forth Dimensions vol II, number 1. LeVan's entire solution fit comfortably in only 3 screens. Unfortunately it omitted all comments, even stack comments, and used short but unenlightening array names such as a, b, c, and x. No wonder the algorithm was hard to follow!

Well, I wondered, is it possible to present the 8 Queens solution readably in Forth? See Listing 1 for my attempt.

The problem is to place 8 Queens on an 8x8 chessboard so that no Queen is under attack by any other. At first I thought I'd need an 8 x 8 array to rep-

resent the board. Each element would be on or off to represent whether a Queen was present on the square. A Queen cannot be placed on a square that is already under attack, so I added an 8-element array to indicate whether any Queen was attacking a particular column, another 8-element array to indicate whether any Queen was attacking a particular row, and two 15-element arrays to indicate whether any Queen was attacking a particular down-sloping or up-sloping diagonal.

After further study I realized I could dispense with the column array. As we place the Queens from left to right, only one Queen at a time in each column, we know there cannot already be a Queen in the column we are about to use. Then I saw how a single 8-element array could represent the board. Each of the 8 elements could represent a column and hold a row number, or it could represent a row, and hold a column number. I decided to let each element represent a row and hold a column number. This makes the array do double duty. It holds the information needed to draw the board and it indicates whether a particular row is under attack.

I saw no way to eliminate the two diagonal arrays. It so happens that all the squares in a given diagonal can be converted to the same number. The row and column numbers of the squares in each down-sloping diagonal have a common difference, e.g.

(1,1), (2,2), (3,3), ... have a difference of 0,  
(2,1), (3,2), (4,3), ... have a difference of 1,

while the row and column numbers of the squares in each up-sloping diagonal have a common sum, e.g.

(7,1), (6,2), (5,3), ... sum to 8,  
(6,1), (5,2), (4,3), ... sum to 7.

Figure 2 illustrates this, and the last two screens of Listing 1 show the corresponding source code.

There are 15 diagonals in each direction. The phrase `- 7 +` converts a row and column to an index between 0 and 15 for the down-sloping diagonals. The phrase `+ 2 -` converts a row and column to an index between 0 and 15 for the up-sloping diagonals.

### The Algorithm

There are 8 Queens to place, one in each column. The heart of the solution is the recursive word `PLACE`. We call it with a row and column number. It checks whether that square is under attack. If so, it simply returns. If that square is not under attack, `PLACE` marks that square as having a Queen. Then it checks to see whether the column number is 8. If so, we have a solution, because a Queen has been placed successfully in all 8 columns, and this instance of `PLACE` "prints the board" and cleans up after itself by unmarking the square it just marked. If the column number where it just marked a Queen is not equal to 8, then it calls itself 8 times, once for each of the squares in the next column, and then unmarks the square it just marked. Note that "it" didn't just mark 8 more squares, it only marked one square. "It" did, though, invoke 8 other instances of `PLACE`, each of which may or may not have marked and unmarked a cell and perhaps invoked an additional 8 instances of `PLACE`, etc. Is this clear as mud? Let's walk through the source code, maybe it'll get clearer.

Screen 1073 merely loads the code in the other screens. Screen 1074 sets up the arrays. `CREATE ROWS 8 ALLOT` sets up an 8-byte array named `ROWS`. When `ROWS` is later executed, it returns the starting address of this array. `: ROW ( row - a) 1- ROWS + ;` defines the word `ROW` which takes a single argument, a row number between 1 and 8, and converts it to a number between 0 and 7 by subtracting 1, and adds this offset to the array `ROWS`. Thus, the address of the byte corresponding to the row number is returned. ("Returned" means left on the stack; all arguments are passed on the stack.) So, we have a "smart" array, or at least `ROW` is a smart array-handling word, in that it lets us use row numbers 1 through 8 and automatically converts to the proper offsets.

Then (still on screen 1073) the arrays `\DIAGS` and `/DIAGS` are created in the same manner, but each is `ALLOT`'d 15 bytes. Their array handling words, `\DIAG` and `/DIAG` are even smarter. They take as arguments row and column numbers and convert them to the proper offset and add that offset to the start of the array. Remember our old friends, the phrases `- 7 +` and `+ 2 - ?` Note that all three words `ROW`, `\DIAG`, and `\DIAG` return the address of the element we want. It will then be up to our code to do something with that address, such as storing something into it or reading (fetching) the value out of it.

Screen 1075 defines some little helper words. We could do without them, by writing out the insides of their definitions every place we need them, but I think they help make the later code more readable. `ERASE` takes an address and count and fills that many bytes with zeroes. It is already built into many Forths. `ON` and `OFF` take an address of a byte and store either all ones or all zeroes into the byte. (`C!` takes a value and address and stores the value into the byte at the given address.) `ON` and `OFF` are commonly used to work on 16-bit words (2 bytes), but for our convenience we redefine them to work on single bytes. `LAST-COLUMN?` should be pretty obvious. It takes a column number and returns true if the column number is 8, otherwise it returns false. `BUMP-ROW`

takes a row and column and adds a 1 to the row number without disturbing the column number. Certainly these last two definitions could be left out, but then we might stumble over `1 +UNDER` without quite realizing what it is doing, i.e. bumping up the row number. `8 =` is clear enough as to what it is doing, but saying `instead LAST-COLUMN?` reminds us why we are doing it.

On screen 1076, `RESET-BOARD` takes no arguments and returns none. It fills all three of our arrays with zeroes. `MARK` takes a row and column as arguments and returns nothing. Note that its definition is divided into 3 separate phrases, with some spacing between them. The spacing (at Wil Baden's suggestion) is usually used to indicate the parameter stack again contains the same items (not necessarily the same values) as the last time the contents were explicitly shown. When `MARK` is called the stack is expected to contain a row number and a column number. The first phrase makes a copy of these numbers (`2DUP` duplicates two numbers) and uses up these copies. Thus at the beginning of the second phrase, the stack once again contains the row and column numbers. The first two phrases set the proper element in `/DIAGS` and `\DIAGS` on. The third phrase is a little trickier. It converts the row number to the address of the proper element of `ROWS` and then stores the column number into that element. `UNMARK` simply undoes everything `MARK` did.

In screen 1077, `MARKED?` takes a row and column number and returns true if the byte stored at the row-th element of `ROWS` matches the column number. In other words, it returns true if a Queen is currently sitting on this square. `DANGER?` takes a row and column and returns true if that square is under attack. It does it by `OR`ing the proper element of `ROWS`, `\DIAGS`, and `/DIAGS`, which say whether the square is under attack by another Queen in the same row or diagonal. It uses the words `PUSH` and `POP` (called `>R` and `R>` in some Forths) to move a number off the data stack to the return stack and then back again.

Screen 1078 defines words to print the chessboard. The dot at the beginning the the word name stands for "print." Borders at the top and left show row and column numbers. A "Q" or an "x" shows that a Queen is or is not present in that square. `FOR ... NEXT` takes a single argument saying how many times to do the loop. If the number is zero, the loop is not entered at all. `CR` outputs a carriage return. `4 .R` takes a number off the stack and prints it right justified in a 4-character field. The body of an `IF ... THEN` is done if the flag on the stack is non-zero. `EMIT` prints one character. In `SQUARE`, `EMIT` prints either a "Q" or an "x" and the "c" in the stack comment just before `EMIT` stands for 'character,' even though I've often used "r c" to stand for "row column."

In screen 1079, `PRINT-BOARDS` counts the number of solutions we have found, and prints out the first few (based on the value of the constant `#BOARDS-TO-PRINT`). `1 #BOARDS` increments the value of the variable `#BOARDS`. `#BOARDS @!` puts the contents of the variable `#BOARDS` on the stack, and `U.` prints that value as an unsigned integer. `?SCROLL` tests the keyboard and pauses the display if a keypress is waiting. In Pygmy you can stab out blindly and stop the scrolling by pressing any key, as long as the loop contains `?SCROLL`. Pressing another key restarts the display. Pressing `Esc` aborts the execution altogether.

All that is easy enough, but we have two words left. Look at the definition of `8QUEENS` first. This is the highest level word in the application, and what you actually type from the keyboard to get the solution. It resets the board to make sure the arrays start out empty. It stores a zero into the variable `#BOARDS`. Then it calls `PLACE` 8 times, once for each square in the first column. `PLACE` will take care of calling `PLACE` for all the other columns. Finally, look at the definition of `PLACE` in screen 1080 and compare it to the discussion earlier about what `PLACE` should do. Note the use of the word `PLACE` (on line 12 of screen 1080) inside the definition of `PLACE`. Here we want the word `PLACE` to invoke another instance of itself, rather

than invoking some other previously defined word that just happened to be named PLACE. The word RECURSIVE fixes up the word we are defining so it can call itself. The RECURSIVE is only active at compile time and does not become part of the final definition. RECURSIVE could have been placed anywhere in the definition prior to the calling of PLACE. Some Forths omit the word RECURSIVE and use the word MYSELF or RECURSE instead of PLACE to accomplish the same thing. Listing 3 shows the output produced by 8QUEENS.

There you have it. Is it readable? I enjoyed working it up in Forth before having to program it in C. It was pleasant to be able to test the individual words, and inspect the contents of variables and arrays, all from the keyboard.

*Among other things, Frank makes EPROM programmers affordable by everyone. If you would like a flier about his Bare Bones EPROM Programmer Kit, from plans, to partial kit, to fully assembled, send him a SASE at 809 W. San Antonio Street, San Marcos, Texas 78666.*

# Real Computing

By Rick Rodman

## 32-Bit Systems

All Readers

## BSD 386, MINIX

---

*Thanks to Rick! don't talk about MINIX in THE COMPUTER CORNER these days. He has a much better handle on the 32-bit world than I do. I keep thinking about getting a real computer, but not sure which one to get. This time Rick gives us the latest news, saving the "what to get" for a later issue. BDK.*

### Linux and BSD 386

Linus Torvalds of Finland has released the source for a 386-specific clone of the BSD Unix kernel, which he calls Linux. This is available by anonymous ftp from various places, which is to say I don't have a copy yet. Also, a "bootable" version of BSD3 86, a non-AT&T version of real BSD for the 386 or 486, has been released by Berkeley for ftp access. There are some folks working on porting each of these operating systems to the PC-532.

What's going on with Mach, you ask? My, we live in interesting times indeed.

### Embeddable CP/M

Years ago, a friend of mine put a row of 2708 EPROMs on his homebrew computer with a complicated counter circuit. These EPROMs contained the CP/M CCP, BDOS, and BIOS. On cold and warm boots, CP/M was loaded from these EPROMs into RAM. While it still had to log in the A: device, the speed of this system was quite remarkable.

EPROMs are available today in capacities of 512 kbytes per chip - for far less than we paid for 2708s in those days. Why not put Z-system in a chip? Tell system designers where in the chip to

put their BIOS, and put the whole shmeer in EPROM? Cheap PROM burners are limited to 27256s or 27128s, so it'd be better to use one of these sizes.

The reason for the clumsy counter circuit was because the CCP and BDOS maintain internal variables within themselves. To make the Z-system run from PROM, it should move these scratchpad variables into the base page of the system somewhere. As I recall, there were very few of these for CP/M; I fiddled at one time with changing them to point to RAM and running CP/M from a Bytesaver II many years back.

### Protecting Idiots from Themselves

Both DR-DOS 6 and MS-DOS 5 have added a bunch of "idiot protection" stuff in them. This is the very stuff which makes technically aware users less and less happy with DOS. The worst is what they've done to the FORMAT command, which won't really format the disk unless you add a "/u" option - and sometimes won't even do it then!

In my experience, it's a safety procedure to reformat floppy disks when I re-use them. This refreshes the magnetic fields of the ED marks and ensures that the whole disk is usable. With these new DOSs, reformatting is a real pain. Another thing that's gone is using DISKCOPY's "formatting while copying". While they may say it still works, in practice it doesn't. You have to format all the target disks first.

What in the world is the industry thinking with respect to DOS? That it's only for stupid users? Neither OS/2 1.3 nor 2.0 has any of this "stupid user" logic.

### Minix News

Andy Tanenbaum has officially released new compilers for Minix in a separate package. ANSI C, Pascal, and Modula-2 compilers are included, in object code form only. Andy claims that the source code would be of no interest, as it was "generated" with the Amsterdam Compiler Kit. (Maybe I'm old-fashioned, but to me, "source code" is by definition the original form of the code, that which the human programmer wrote; anything "generated" is "source" but "object".)

There was some discussion in which the compilability of Minix 2.0 appears to come into question. First, Andy wrote: "It is my intention to go over to the ANSI C compiler for MINIX 2.0. In fact, I have been running nothing else but the ANSI compiler for over a year, and it seems pretty solid." This new compiler will not come with Minix, even in binary form. However, Andy also says: "Most of version 1.6.18 is already ANSI-fied. Never theless, as much as possible, I will keep the 2.0 code such that it can be compiled with the old compiler, so you don't have to switch to the new ANSI compiler if you can't afford it." Note the use of the slippery phrase, "as much as possible". The size of the grain of salt necessary is left to the reader's imagination.

The Modula-2 compiler also includes a "makefile generator". The package is available from two companies, which are listed at the end of this column, for about \$200.

The shocking rumor has been confirmed: Minix for the Atari ST and for

the IBM PC are not file-system compatible. It is not possible to exchange Minix disks between the two. The reason for this is that, while the 8088 and 68000 are known to use different byte orders (the 8088 is "little endian" and the 68000 is "big endian"), Andy Tanenbaum and his programmers made no effort at all to standardize on a byte order. Thus, a historic opportunity for cross-platform portability was carelessly discarded.

Minix experimenters are put on notice that Andy Tanenbaum, who has said many times that he regards Minix as a "hobby", has little concern for their attempts to do real work with this operating system. I'm personally very disappointed, because Minix is, after all, one of the most expensive PC operating systems available.

In happier news, I recently added a SCSI floppy to my PC-532, and used it to transfer a great many files. The PC-532 is compatible with the PC Minix file system and can exchange disks with PCs running Minix. Also, the MIN2DOS package, which allows reading and writing Minix floppies from the PC, can be used to transfer data from DOS to a Minix floppy.

A SCSI floppy? Yes, they are available. This one is a TEAC FC-1-01, and can read and write any 3-1/2" format up to the 3.88-megabyte "ED" capacity. It's available for about \$200 from J. D. Hannam. ED diskettes at my local CompUSA sell for a stratospheric \$80 per box, so I won't be buying any of those real soon.

#### Free Ideas

Here are some ideas that'll make somebody lots of money. (If it's you, remember where you read them.) In the past, you had to get something to work to get a patent, but the Gilbert Hyatt and RS A cases show that you can get a patent today for almost anything, just on the basis of chicken scratches on the back of an envelope. I don't agree with this, so I'm not patenting them, but if someone does, this article will constitute equivalent prior art. Anyway, these are prod-

ucts I would expect to see soon, probably all before the end of 1993.

**3-inch CD-ROM:** CD-ROM will really hit stride as a software distribution medium when 3" CD-ROMs come out. The 5-inch CD-ROMs are just too big, both physically and in byte capacity (600 megabytes). While CD3 audio disks were a flop, the computer industry is different. Another factor will be Kodak's Photo CD product, which will drastically reduce the cost of producing CD-ROMs in small quantities. CD3-ROMs, with 160 to 200 mega bytes, will play in your regular CD-ROM drive with an adapter.

**Portable teleprompter:** This would be just the thing for people who are giving presentations or sales pitches. While electronic organizers are popular now, none have this feature. The display should "crawl" with smooth scroll at a slow rate, but allow the speaker to discreetly stop the scrolling, or scroll forward or back.

**Self-aligning printer:** By adding inexpensive optical sensors to a printer, the printer can recognize lines or boxes on a printed form and automatically align to the form for printing. This fits into the major trend toward smarter printers. **Printed food:** Computer-driven systems with CCD cameras for automatic alignment will spray precisely-patterned food coloring on mass-produced food items, producing snack foods and other items with logos of sports teams and popular entertainment stars, as well as advertising. As this industry matures, photograph-like images will become possible. This will be a major fad at first, but become commonplace as time goes on.

Personally, I find the idea of printed food unappetizing, but given recent history, you have to admit it's inevitable. Virtually everything is an "advertising vehicle" these days, and people love it - they actually pay for the privilege of advertising sports teams and rock stars by buying T-shirts and other stuff at premium prices. Printed-food technology will be quite clever and involve major investments in hardware and

engineering talent - which could mean you.

How about it, readers? Am I all wet? Maybe I can get the Editor's permission to send a sporty TCJ Coffee Mug (or a bag of TCJ Potato Chips?) to the first reader to spot a commercial implementation of any of these ideas. Have more ideas along these lines? Send 'em in, and see your name in genuine print!

#### Next Time

Next time we'll discuss IBM's OS/2 2.0 - from an experimenter's perspective. For example, I'll describe how to run Minix within OS/2. Plus I'll have more insight on using the SCSI bus in new and wondrous ways. 'Til then, remember, you don't need windows when it's warm and sunny.

# Kaypro-84 Direct File Transfers Without Null Modem

By Walter J. Rottenkolber

8-Bit Systems

Intermediate

Data -1/0

Although this is a mostly Kaypro upgrading project, I was interested in the simplicity of the project. All too often we pass over the easiest way for a more complex or traditional answer. It got me thinking and I hope it stirs your own little gray cells into some work. BDK

If your Kaypro is one of the 1984 or newer versions, you can do direct computer to computer file transfers without needing a null-modem cable or adapter. These Kaypros have two serial ports - modem and printer - configured differently. The modem port is wired as Data Terminal Equipment (DTE), whereas the printer port is setup as Data Communications Equipment (DCE). As a result, the printer port of one computer can be connected to the modem port of another with an ordinary RS232-C serial cable.

The only catch is that modem programs are (naturally) configured for the modem port. So you need to redesign a modem program to operate through the printer port. This is easily done on the modem configuration overlay because only the baud port, and the SIO data and control port addresses need to be changed.

Since the same type of chips are used for both ports, no changes are necessary for register numbers, control codes, and bit masks. Fig. 1 shows the SIO port addresses, and Fig. 2 is an abbreviated example of the changes to the IMP245 Kaypro overlay.

I found that MEXI14 could handle up to 4800 b/s reliably in direct file transfers, but that IMP245 could go up another notch to 9600 b/s without choking. Seeing those kilobytes flash by made IMP the best choice. One peculiarity of IMP

shows itself in batch mode. Searching for filenames and placing them in the name array takes an unexpectedly long time. If the batch has more than about seven file names, the process can take long enough for the receiving system to timeout. In one batch of 36 files, it took

almost four minutes to process the filenames before transfers began.

Unfortunately, no message alerts you when filename processing is over. You will simply have to find by experiment the time to delay before starting the batchfile receive.

FIG. 1

Port Addresses

Modem (DTE)	Printer (DCE)
Baud --	OOH OCH
SIO Data -	04H OCH
SIO Ctl/St -	06H OEH

FIG. 2

MP245 Kaypro Overlay Changes

```

PORT EQU OCH ; Your base port (data or status)
MDCTL1 EQU PORT+2 ; Modem control port
MDDATP EQU PORT ; Modem data port
MDRCV EQU 01H ; Modem receive ready
MDSND EQU 04H ; Modem send ready bit
MDTXE EQU 01H ; Modem send buffer empty, holding buffer empty
;
BRPORT EQU OBH ; Baud rate generator port
;
; These routines and equates are at the beginning of the program so
; they can be patched by a monitor or overlay file without re-assembling
; the program.

*When calling AM Research, you will talk to ' Mitch. ' ' That is Al Mitchell himself; designer, engineer, and Forth programmer. Mitch has designed and built several 80451 development systems. He uses FPC for the basis of his embedded and interactive development platform. A special Forth 80451 kernel resides on the chip and you debug and develop your product using code written on a PC that is then down-loaded and run under your control. It is pretty close to something I might have developed myself (given lots of time and money - but then I could also be president.)*

*Fortunately I don't need to develop it myself, as Mitch has done a very good job. Part of his package includes sample code and projects. I got him to give us the low down on how he produces DTMF analog signals (one of the sample projects included in his manual.) You could do this using \$3 to \$10 worth of D/A conversion, or you do it his way for 30 to 40 cents worth of easily available parts.*

*I listed this as an intermediate project due to the op amp design, but beginners will be able to figure out what is happening if you dust off a textbook on amplifiers (find the section on summing amps.) Actually this is a rather easy concept to get if you just hang in there and read on, so read on! BDK.*

A recurring theme in our applications work has been to generate signals under the control of a microprocessor. While this is relatively easy using a DSP or other powerful processor, doing so with cost-effective components requires finesse

and elegance rather than brute horsepower.

One such example is a remote, stand-alone data acquisition system which needs to download data on occasion. This application required only a single 8051-type processor for the task. Since it also had to dial the telephone, generating Dual Tone Multi-Frequency (DTMF) signals, the software required more than conventional techniques.

In this first of a series of articles we will discuss the theory of creating the precise analog counterpart to a digital data byte. The next article will describe the program and code requirements to drive the circuit in real time. Following articles will discuss alternative methods appropriate for differing applications.

Two methods of Digital-to-Analog (D/A) conversion can be constructed with relative ease. The first is commonly called a "Weighted Resistive Ladder" wherein each digital signal input (or ladder rung) has half the resistance of its predecessor. The inputs are derived from the parallel port of the microprocessor used. A voltage (analog voltage) is produced which is equal to the additive voltage/current produced across all the resistors in the ladder.

Whether voltage/current is added into the circuit, depends on the state of the parallel line attached to a given resistor. The amount of additive signal is controlled by the voltage drop across the individual resistor. The minimum and maximum values of resistance are therefore related by a binary relationship, I. E.:  $2^n$ . In this case we are constructing an eight bit A/D so the relationship of

the largest resistive value is  $2^8$  or 256 times the value of the smallest resistor.

Both the maximum and minimum values are limited by components and construction method used. In our case, constructing a prototype wire wrapped PCB, the maximum reasonable value you can use is about one Meg ohm due to humidity, stray capacitance and availability of components. I prefer to use less than the maximum value for stability and reliability reasons. Lets check the minimum value which is  $1/256$  of  $R_{max}$  or roughly 4K. ohms. The first pass of our design is shown in figure 1.

Using the quasi-bidirectional port of the 8051 reveals that the output structure looks like a 30K pull-up resistor with an open-drain MOSFET pull-down (the internal components of the 8051.) This is a serious limitation since the 30K pull-up would be added to value of our resistor selection giving unacceptable performance. This can be overcome by using a CMOS driver, like the 74HC04 which will buffer the 8051 and provide very low output impedance of roughly 100 ohms. With proper drive we can now plug in the resistor values.

The output voltages can be easily determined by considering the input of the summing amplifier to be one-half the full scale voltage of  $V_{cc}$  or 2.5 volts. In describing the circuit operation we need to keep in mind that we will be generating a sine wave oscillating between  $V_{cc}$  and ground. This means that our reference is better described as 2.5 volts. The 2.5 volt reference is produced by using a low pass filter to average the sine wave

and to provide feed back to the op amp non-inverting input.

Ri then either provides a positive or negative current, relative to the summing node of the operational amplifier, of  $(V_{cc} - V_{cc}/2)/1K$  or 2.5 milliamperes. The op amp operation is to invert attempts to counterbalance this input current trying producing an output which brings the inputs to an equal value (the results of feed back signal.) Therefore the output swings to a value of 2.5 Volts plus or minus  $(470 \times 2.5\text{ma})$  or feedback resistor times current) 1.18 volts. Therefore the MSB drives the output to either 3.68 or 1.33 volts. Additional inputs to the network will combine to provide an output swing of roughly 0.15 to 4.85 volts.

Previously we determined that the maximum resistor size can be as high as one Meg ohm, circuit stability can be improved by using lower values so let us select 1.0K for the Most Significant Bit (MSB). It then follows that each successive resistor should be twice that value. Since most of us only have easy access to 5% resistors we must construct the resistors needed from easily available and standard sizes. Below is a listing of our selections:

Calculated Value	Rough Approximation	Finely Tuned
R1 = 1K	1K	910 ohm
R2 = 2K	2K	1.8K
R3 = 4K	3.9K	3.9K
R4 = 8K	7.5K	+510 ohms 7.5K
R5 = 16K	15K + 1K	15K
R6 = 32K	27K + 5.1K	27K
R7 = 64K	62K + 2K	62K
R8 = 128K	120K +	8.2K 120K
R9 = 470 ohms		
R10 = 1Meg		
C1 = 10 ufd		

Note that the column entitled "Finely Tuned" uses a common trick of trimming standard resistances to the exact value needed using a needle file and DVM. Although this circuit is not critical in the need for specific resistor types, carbon composition are easiest to trim, they have a carbon granule core which is fairly soft and easy to grind away. Carbon and Metal Film resistors are vapor deposited upon a ceramic core and con-

siderably more difficult to modify. All can be altered however by removing conductive material which increases the resistance.

Using a Digital Volt Meter we were able to get the exact resistance needed by a combination of selected series resistors. Should the selection not be available simply file the body of the resistor until the value desired is achieved, just make sure to seal the injury to prevent moisture contamination. If you go slightly too far the carbon varieties can be lowered a small amount with the judicious use of a hot soldering iron tip at the contact point. Note that resistors modified in this manner may change resistance slightly when soldered so it is a good practice to heat and stabilize them anyway.

The advantage of the weighted resistor network is that anyone with simple equipment can quickly construct an accurate D/A converter without rare component values.

A second economical method of D/A conversion uses the 'R-2R' method. In this configuration only two resistances are needed regardless of the ultimate bit length required and therefore is most common in high resolution designs and on dedicated D/A integrated circuits. The wide disparity of resistance values, and temperature coefficients, are significantly decreased resulting in better accuracy.

The limitations are similar to the "Weighted Ladder" above as to drive

requirements but the use of one value eases construction considerably. In place of the "2R" component two resistors can be used in series. Therefore three resistors of one value are needed per bit of input.

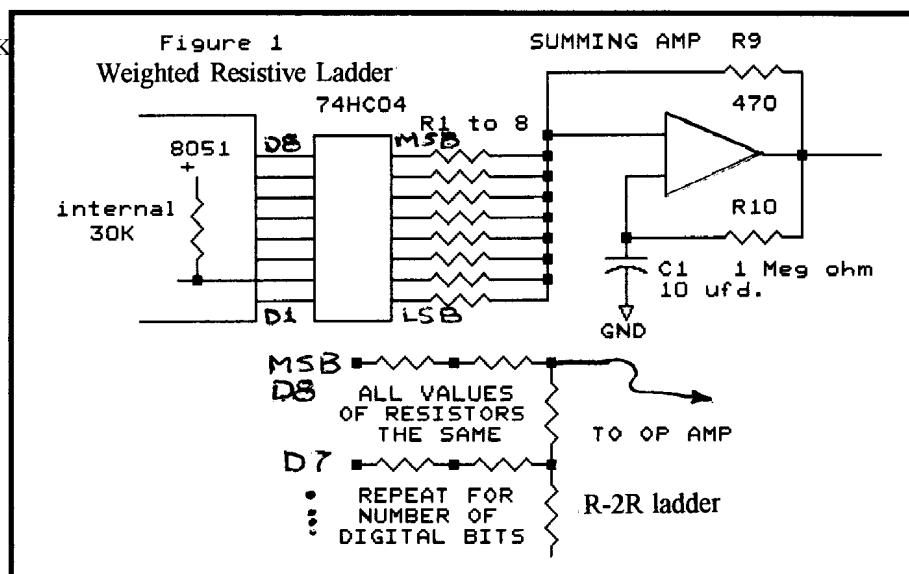

This is an excellent circuit when time, or bench stock, permits the use of standard precision parts. Note that the precision required is quite substantial with tolerance buildup although 1% components are usually sufficient for an 8-bit D/A.

The calculation of specific digital values is not difficult. Beginning with the summing amplifier reference equivalent to half scale, one can see that if the MSB is low (up output inverted) then the output of the summing amplifier is  $-(V_{cc}/2R) \times R$  plus or minus the binary values of the remaining bits.

The advantage of the R-2R ladder D/A converter is that one single resistor value is used which can be constructed without special techniques.

Other more esoteric methods of signal generation will be covered in future columns.

*Al Mitchell runs AM Research from 4600 Hidden Oaks Lane, Loomis, CA 95650 (call (916) 652-7472. He has been building embedded system for many years. When not building you can find him in his large garden, working away the hours.*

Peer-To-Peer LANs

## Computer Corner

By Bill Kibler

**W**hen our house move is completed but organization is far behind. I have a new home office and shop combination that will be pretty good when it gets all set up. That "when" however could be sometime long in the future as there are plenty of more important items in the queue to be done first.

For work, my direction has moved away from the 68000 and into LAN problems. We have received the latest version of LanMan 2.1 and are working with the problems it created. I have also been spending considerable time with Novell's NetLite product.

### NetLite

Netware products have been mostly aimed at the major LAN user. The problem with that is the cost associated with even a two or three user network. Novell has no price break in essence for size of network. Complexity of Netware products is rather high as well. Special schools are necessary to service the LAN as their manuals do not explain all. Some changes have been made over the past few years but if you are a small user, generally it is more problems than it is worth.

Starting with the \$25 network and now with several vendors making LAN based systems for the small user, Novell has entered the market. The \$25 network is a serial based system for up to three users. I have it and it works just fine for small setups. For larger groups up to 25 users Netlite is now available. For more than 25 users, there are other systems. Our company did test three of the products and found Netlite the poorest of the group. At this stage I would recommend

any of the other products as I will explain.

Netlite installs easily and does seem to work as advertised. If you happen to have any problems however, there is no way to get answers. Novell's own technical support group has not had a chance to learn about the product yet. Also the manuals are absolutely no help if it doesn't work. Our problem has to do with NETBIOS calls, and as I found out may be a problem in all Netware products.

We use NETBIOS operation to pass data between our mainframe and remote terminals. We have had some problems with vendors implementation of NETBIOS. NETBIOS was IBM's original method of interfacing to the LAN. It since has become a hardware and manufactures independent interface to the LAN network. However each vendor must implement their own version of the standard network interface. It is very similar in concept to DOS calls. NETBIOS has a standard interrupt you call with a pointer to a NCB, NETBIOS CONTROL BLOCK. The NCB contains pointers to where the data is, who it goes to, what operation is to be performed, and where to post the results of that operation.

As a programmer you can write code to this interface and should have the same results on any vendors setup. We have found that not to be completely true. Some of IBMs implementation stole keystrokes or turned off our interrupts. 3COMs old version of NETBIOS bounced when first started. 3 COM has solved the problems in their latest release. Netwares NETBIOS appears to work fine on Token ring but fails on

Ethernet systems. If you are running a versions of these products you might try COMPUSERVE. We have downloaded new versions of 3COMs and Novell NETBIOS programs from there.

Speaking of downloading, I have found out that you could make a complete LAN system by using FREE upgrades from CompuServe. In working with NetLite I discovered that the device drivers and NETBIOS driver are available to be downloaded. They are intended as upgrades for their current users. They will work as a NETBIOS system as they are. This means no security, or fancy DOS interfaces. However combined with other FREE NETBIOS programs it is possible to have a system that can pass files between stations, run programs remotely, send message to other users, and even create multi-user type systems.

I have tried several of the free NETBIOS programs with varying results. Some worked very well, others only locked up and died. There is of course no support for these systems, but the cost is very reasonable. I plan on trying to pickup some older Ethernet cards and try my hand at multiple processor operations using NETBIOS calls. Since I program using NETBIOS operations that should be a easy task. For most, the programs on the BBSs or from books will have to do. There appears to be only two books available. "C: programmer's Guide to NETBIOS", by David Schwaderer, and "Network programming in C" by Barry Nance.

I have bought Nance's book and it comes with programs on disk. The programs work and his book makes an excellent reference manual. Our company product was built using help from Schwaderer,

and disks are available by mail. The references in Schwaderer are very good on regular NETBIOS operations, but Nance also covers Novell's IPX/SPX interface. Examples in either book do appear to work and provide a sound basis for making your own NETBIOS to NETBIOS system.

The Netlite structure is based on TSR device drivers. These TSRs programs provide communications with the LAN interface card and NETBIOS. For Netlite a Client and Server TSR provide interfaces into DOS creating the peer-to-peer network. Most big networks work off the idea of a single server computer that controls who and what users can do. All common files are maintained on the server and other users normally would not have access to other users data without it first being put on the server hard drive. The server as such becomes a very small mainframe system. This means one system is dedicated for LAN control and data storage only.

In small organizations, the use of the LAN is for message passing, sharing of printers, and limited data or file sharing. Many small organizations would be happy to eliminate hand carrying of floppy disks from system to system. The peer-to-peer LAN systems are designed for this market. No servers are needed or all users can be servers. The design concept is that all users have the same options and can setup their station as the situation warrants.

Other magazines have reviewed these small LANs and most like Novell's approach to explaining the how and why of peer-to-peer systems. Cost is basically \$99 per user including hardware(LAN interface card). Novell was able to produce their product quickly and cheaply by only writing two new programs. Their Client and Server programs appear to be cut down versions of other parts of Netware systems. This means that all the device drivers are the exact same ones as used on the bigger Netware system. In fact they use ODI drivers completely. ODI is a standard device driver interface that you could create yourself if needed. I have been thinking about do-

ing just that for a serial based ring, but that is another subject.

The bottom line is we have found a very special problem in Netlite and Netware in general. It appears that given data packets back-to-back the NETBIOS interface will ABEND or die. It ABENDs so bad that in most cases you must power down the system to bring it back on line. Doing so of course prevents you from checking your data in anyway to find out what happened. I modified our device drivers with EFORTH and was able to do some crude debugging even after an ABEND. The only way out of the device driver after running EFORTH and getting my data was the power switch.

If you are starting to get the idea that working with LANs is complex, expensive, and problematic, you are getting the correct idea. Novel called about the problem and wonder if we could send over some of our stuff so they could see for themselves what the problem is. My comment was a question, it needs a mainframe, special interface software, several stations, or about a quarter million dollars in hardware and software systems to make it work. As I have said before, working on LANs and most new systems is no longer a little garage type operation. These systems cost money, lots of money, and take lots of time and resources to make work.

#### **68HC16**

To move on to another good topic is Motorolas newest trainer board. I bought one of the DSP (digital signal processing) trainer kits. For \$168 it is a great buy. So when you get tired of fighting the big boys, try these little boxes. The software and hardware is excellent. The HC16toolkit is an excellent trainer. I have already started on the books, and believe me there were plenty of books included.

You get two boards in this set, the 68HC16 evaluation board and an stereo signal interface board with display. The project looks like fun and I will report more about it later. If you did not get one, try and borrow one from a friend.

When it comes to supporting their users, hardware users in this case, Motorola still is number one in my book.

#### **ENOUGH**

I said enough this time and had enough to do with LANs for the day. Next time I will explain more about the HC16 trainer and its features. I hope to have finished the project with it and may be able to comment on DSP system better after the project. Keep hacking.

## Stand-Alone Gang Programmer

- 8 ZIF Sockets for Fast Gang Programming and Easy Voltage Splitting
- Completely stand-alone or PC driven
- Programs E(P)ROMs
- 1 Megabit of DRAM
- User upgradable to 32 Megabit
- .3/6" ZIF socket, RS-232, Parallel In and Out
- 32K internal Flash EEPROM for easy firmware upgrades
- Quick Pulse Algorithm (27256 in 5 sec, 1 Megabit in 17 sec.)
- 2 year warranty
- Made in U.S.A.

Technical support by phone

- Complete manual and schematic
- Single Socket Programmer also available. \$550.00
- Split and Shuffle 16 & 32 bit
- 100 User Definable Macros, 10 User Definable Configurations
- Intelligent Identifier
- Binary, Intel Hex, and Motorola S

20 Key Tactile Keypad (not membrane) 20 x 4 Line LCD Display

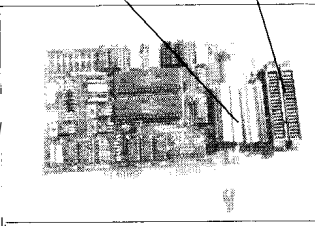

## \$750.00

## Internal Programmer for PC

New Intelligent Averaging Algorithm. Programs 64A in 10 sec., 256 in 1 min., 1 Meg (27010,011) in 2 min. 45 sec., 2 Meg (27C2001) in 5 min. Internal card with external 40 pin ZIP.

- Reads, verifies, and programs 2716, 32,32A, 64, 64A, 128,128A, 256, 512, 513, 010, 011,301, 27C2001, MCM 68764, 2532
- Automatically sets programming voltage
- Load and save buffer to disk
- Binary, Intel Hex, and Motorola S formats
- Upgradable to 32 Meg EPROMs
- No personality modules required
- 1 year warranty 10 day money back guarantee
- Adapters available for 8748,49,51,751, 52,55, 1 TMS 7742,27210,57C1024, and memory cards
- Made in U.S.A.

### A New Project

Our line of macro Cross-assemblers are easy to use and full featured, including conditional assembly and unlimited include files.

### Get It To Market-FAST

Don't wait until the hardware is finished to debug your software. Our Simulators can test your program logic before the hardware is built

### No Source!

A minor glitch has shown up in the firmware, and you can't find the original source program. Our line of disassemblers can help you re-create the original assembly language source.

### Set To Go

Buy our developer package and the next time your boss says "Get to work.", you'll be ready for anything.

### Quality Solutions

PseudoCorp has been providing quality solutions for microprocessor problems since 1985.

### BROAD RANGE OF SUPPORT

- Currently we support the following microprocessor families (with more in development):

Intel 8048	RCA 1802,05	Intel 8051	Intel 8096
Motorola 6800	Motorola 6801	Motorola 68HC11	Motorola 6805
Hitachi 6301	Motorola 6809	MOS Tech 6502	WDC 65C02
Rockwell 65C02	Intel 8080,85	Zilog 280	NSC 800
Hitachi HD64180	Motorola 68000,8	Motorola 68010	Intel 80C196

- All products require an IBM PC or compatible.

**So What Are You Waiting For? Call us:**

### fon(h...

When memory, time, and budget are tight, or when your first-choice solution cries out for an extensible language, think of Forth. It's perfect for embedded systems, and is *legendary* for fitting in small places... even places in orbit on the space shuttle. Today, Forth is at home under most any operating system, and implementors offer both lean and rich environments. Join the Forth Interest Group now and learn how well Forth fits in your programming toolbox.
